Voyager Control Manual (version a0.1)

Welcome to Voyager! This document outlines the control interface for the Voyager Software System.

Please be advised that this document is intended for Voyager Version a0.1 only, and will likely change as the software advances toward the full version.

Mouse Control	Appendix A: Quick Reference	8

Suggested System Requirements

To run the current version of Voyager, you should have:

- Windows 7/8/8.1
- 40MB free disk space
- Mouse
- Keyboard

The current version does not support Linux or Mac environments.

Setup Instructions

Follows these instructions to set up and run Voyager a0.1.

Step 1: Download Voyager a0.1.rar

Download the file named 'Voyager 0.1.rar', and place it in a convenient directory.

Step 2: Decompress the Software

Open the .rar file using WinRAR (if you do not have WinRAR, you can download it here). Click on the 'Extract To' button on the top ribbon as shown in Figure 1, and extract the folder to the same directory as the .rar file.

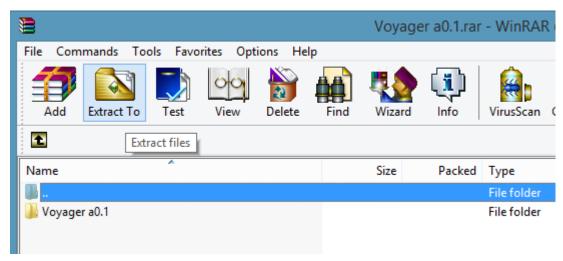

Figure 1 - Extracting from the Voyager a0.1.rar file

Step 3: Running Voyager

Inside the folder 'Voyager a0.1' there will be two items (Figure 2 below). Double click on the 'Voyager a0.1.exe' file to begin the program.

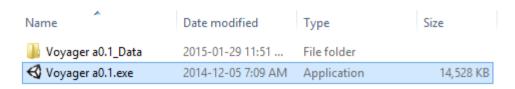

Figure 2 - Items inside Voyager a0.1 folder

A popup configuration window will appear (as in Figure 3) asking for setup input. Ensure that the Windowed box is check marked, and that you have selected a resolution that fits within your screen resolution. The graphics quality does not matter at this point, as all options will result in the same graphics resolution.

When these settings have been entered to your satisfaction, press the 'Play!' button to start the program.

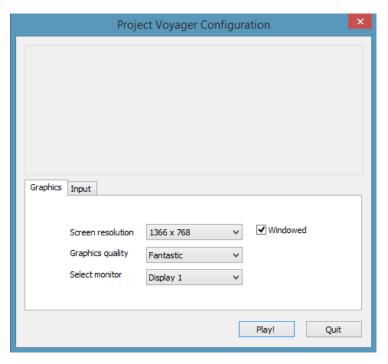

Figure 3 - Project Voyager Configuration window

Using Voyager

The current version of Voyager makes use of several UI windows, text entry fields, and buttons. These will likely be phased out in later versions to make way for a cleaner, context based interface.

Getting Started with the Camera

When the program first starts, you will most likely see a window that looks like Figure 4.

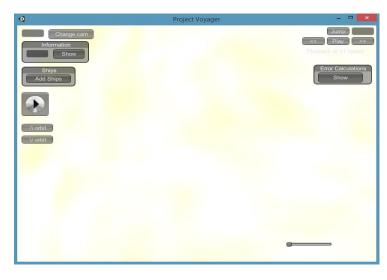

Figure 4 - Voyager opening screen. The camera is positioned very close to the sun.

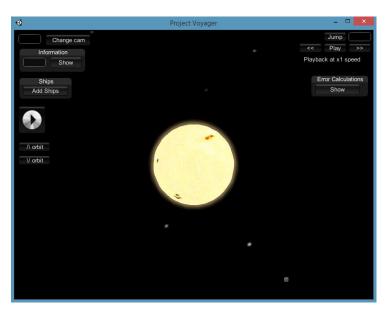

Figure 5 - Once zoomed out, the sun in its entirety should come into view.

Clearly this is not what we want to be seeing.

When Voyager starts, the camera is positioned very close to the Sun [ID: 10] (this is for debugging purposes and will be phased out in a later build). In order to get into a better view, use the mouse scroll wheel and scroll back until your image is more like that of Figure 5.

The scroll wheel can be used to zoom in and out in the Voyager User Interface (UI), and will dynamically slow down as the camera moves closer to the object of focus.

From here, you can click and hold the right mouse button, and rotate the camera about its current target. In this case, the camera's target is the Sun [ID: 10]. The rotation is not limited by the object, so as you rotate and zoom, you can observe all objects from all angles.

Voyager makes use of the NASA JPL Horizons Database in order to determine the location of celestial objects over time, and so the ID scheme for each planet, moon, and star currently rendered in Voyager matches that found in the Horizons Database. For reference, a table of the bodies and their IDs are provided in the quick reference sheets found in Appendix A. For practice, all bodies

named in this document will be written with their IDs noted in brackets. (Ex. Earth [ID: 399])

The User Interface

The tools currently available in the user interface can be used to jump between object in space, retrieve information on objects, and to move the objects back and forth in time. A numbered image of the interface is show in Figure 6 below, and a description of each numbered item follows.

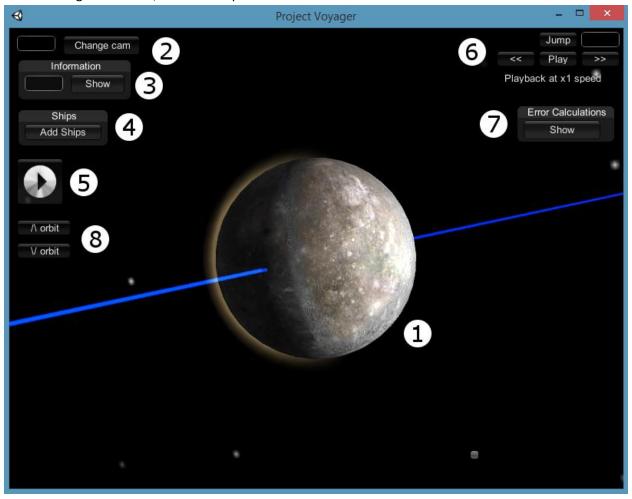

Figure 6 - Voyager UI elements

- 1. The object in the center of the screen is the current *Target*. When you hold down the right mouse button and rotate, or when you use the scroll wheel on your mouse to zoom in our out, the *Target* is what the camera is focused on. When time is moving forward, the camera stays pinned to this object.
- 2. The Change Cam button lets the user switch the current *Target* to another object. This is done by clicking on the entry window to the left of the Change Cam button, and typing in an object ID number. Once the number is entered, you can switch targets by either hitting the *Enter* key on your keyboard, or pressing the Change Cam button on the UI.

It should be noted that if multiple objects are visible in the UI (ex. A planet and a moon), then you can also switch your *Target* by double clicking with the left mouse button on the object you want to switch focus to.

3. The information window allows you to pull up simple information about each object, referenced by their object ID number. To pull up information, click on the entry box and type in the ID number of the object you are interested in. Then click the Show button. A new window with information will appear, and this can be clicked on and dragged to a good location on the screen. To close this new window, make sure that the same object ID is typed into the entry box, and click the Hide button.

At this time, the information is very rudimentary and is intended only for debugging functionality.

4. The Add Ships button allows you to add simple vessels to the interface. To do this, click on the Add Ships button. The window shown in Figure 7 will appear, and allow you to specify the orbital parameters and mass information of the vessel.

Make sure to pay particular attention to the Orbiting Focus entry field, as it designates what object the vessel will be orbiting. Be aware that entering a Semi-major axis value smaller than the radius of the Orbiting Focus body will result in an error message.

When you are satisfied with your parameters press the Add button, and your vessel will be generated.

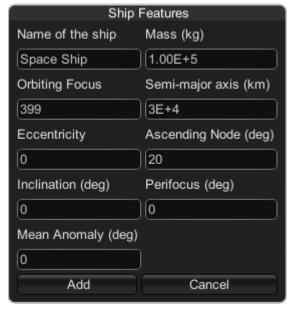

Figure 7 - Ship generation window

The ships are quite small (though not yet to scale), and their orbits are not yet highlighted like those of the larger bodies. If you cannot see your ship, enter 'Ship1' in the Change Cam field, and press enter. You will notice that all ships currently generated are given the model of the Voyager 1 probe, as shown in Figure 8 below.

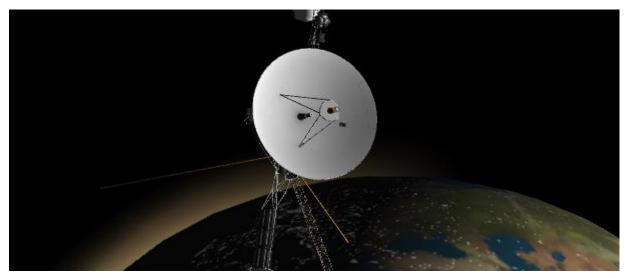

Figure 8 - Voyager 1 probe in orbit around Earth

- 5. The large Play button commands the system to start moving through time at the currently selected speed. This button will be taken out shortly, as the same functionality is better controlled by the buttons described in point 6.
- 6. The time controls let the user move time forward at different rates, with each object traveling on its predicted course over time. To increase or decrease the play speed, simply click on the << or >> buttons (slower and faster respectively). You can press the Play button to set time moving, and press it again to stop time. In order to jump to a specific time index, simply click on the entry box above the controls, enter a time in seconds, and press enter. This method is most commonly used for resetting the time to 0.
- 7. The error calculation window is a debugging window that allows the user to determine the exact position of an object in Voyager at a given time. This position data is provided in Euclidian coordinates with the Sun positioned at the origin for simplicity. This data is used to check against the Horizons database to ensure the accuracy of the planetary and lunar orbits. When the Show button is clicked, a new window will appear as in Figure 9. By entering the object ID number into the entry window and pressing the Fetch button, the exact position data for the specified body can be acquired.

Figure 9 - Error Calculation window

Warning: There is also a slider bar near the bottom right corner of the Voyager UI. This is a separate control for the time speed, and results in very fast motion. It has several bugs and it is not recommended that the user use this UI element at this time.

Appendix A: Quick Reference

Mouse Control

Object ID Number

HORIZONS ID	NAME
	_
10	Sun
199	Mercury
299	Venus
